Code - CSE - 323.

Answer to the Question No-2 - Q

Q Ans: Originating Call: Call Origination is a telecommunication term And generally refers to an inbound call or to the party making call (the call originator). Call Origination is the opposite side of call termination And includes the Activities related to the call set-up, switching and Connection. It is important for a call center to understand the meaning of the call setup, origini Origination as telecom carrier rate sheets often are based on call origination and termination.

⇒ ⇒ for example: Number Type price per minute.

Local \$ 0.0034

Total free \$ 0.00130.

GMSC

MSC - MTE

Handover call: In cellular telecommunication, the term handover or Hand off refers to the process of transferring ongoing call or data connectivity from one base station to the base station when a mobile moves into the different cell while the conversation is in progress. Then the MSC (Mobile switching center) transfers the call to a new channel belonging to the new base station.

When a mobile user A moves from one cell to another cell then BSC 1 signal strength loses for the mobile user A and the signal strength of BSC 2 increases and thus ongoing call or data connectivity for mobile user goes on without interrupting.

Type of Handover call →

- ① Hard Handover.
- ② Soft-Handover.

(b)

Ans: Measure Network performance 'way'

As mentioned above, to monitor the performance from a user point-of-view, we need to perform Network performance tests from that same perspective. Ideally to do so, you want to monitor Network performance from the end-user's location without having to install a Network measurement tool on each user Workstation.

Moreover, you don't want to capture every data packet for analysis. Which will require a lot of Extra hardware and can intrude into your user privacy.

⇒ The most essential Network metrics —

- Latency . In a Network, Latency refers to the measure of time it takes for Data to reach its destination Across a Network . . . . .
- Jitter . . . . .
- paket LOSS . . . . .
- Throughput . . . . .
- paket Duplication . . . . .
- paket Reordering . . . . .
- User Quality of Experience . . . . .
- Most Score . . . . .

## Classification of Routing algorithm.

The Routing Algorithm is Divided two categories.

- ① Adaptive Routing Algorithm
- ② Non-Adaptive Routing Algorithm.

⇒ Adaptive Routing: → In Adaptive routing algorithm is also known as ~~Dynamic~~ Dynamic routing Algorithm.

- This Algorithm makes the routing Decision based on the topology and Network traffic.
- The main parameters related to this Algorithm are Hop Count, distance and estimated transit time.

\* \* \* Adaptive Routing Algorithm can be three part classified

- ① centralized Algorithm.
- ② Isolation "
- ③ Distributed "

⇒ Non-Adaptive Routing Algorithm: → Non Adaptive routing Algorithm is also known a static routing Algorithm.

- When booting up the network, the routing information stores the routes.
- Non Adaptive routing Algorithms do not take the routing decision based on the Network topology or Network traffic.

\* \* The Non-Adaptive Routing Algorithm is of two type:

- ① Flooding type
- ② Random walks .

Answer to the question No - 4 (a)

(a) Ans: Traffic intensity / user =  $7.4 \times$   
 $= 1 \times (1/60) \times 2.5$   
 $= 0.041 \text{ Erl / user}$

for each cell,  $n = 20, B = 10^6$ .

From Erlangs table, The offered traffic,  $A = 17.61 \text{ Erls.}$

$$\text{Number of users/cell} = 17.61 / 0.041 = 429$$

$$\text{Total Number of users} = 700 \times 429 = 300300$$

$$\text{penetration rate} = (\text{Number of users} / \text{Total population}) \times 100$$

$$= (300300 / 4 \times 10^6) \times 100$$

$$= 7.50\% \quad \underline{\text{Answer}}$$

Answer to the Question No - 4 -

⑥ Frequency Reuse: Frequency Reuse is the scheme in which allocation and reuse of channel channels throughout a coverage region is done. Each cellular base station is allocated a group of radio channels or frequency sub-bands to be used within a small geographic area known as a cell. The shape of the cell is Hexagonal. The process of selecting and allocating the frequency sub-band for all the cellular base station within system is called frequency planning.

Fig: Frequency Reuse.

④ Cellular Network: A cellular Cellular Network is a radio network.

Distributed over land through cells where each cell includes a fixed location transceiver known as base station. The cells together provide radio coverage over larger geographical areas. User Equipment (UE), such as mobile phones, is therefore able to communicate even if the Equipment is moving through cells during transmission.

④ Advantages:

- ① Increased Capacity.
- ② Reduced power use.
- ③ Larger Coverage Area.
- ④ Reduced interference from other signals.

[ Factors for determining cell size ]

- b  
→ No. of users
- Multiplexing And transmission tech. used.

Answer to the Question No - 5.

③ Answer: Hidden terminal problem: In wireless LANs (Wireless Local Area Networks) the hidden terminal problem is a transmission problem that arises when two or more stations who are out of range of each other transmit simultaneously to a common recipient. This is prevalent in decentralized systems where there aren't any entity for controlling transmission. This occurs when a station is visible from a wireless access point (AP), but is hidden from other stations that communicate with the AP.

⇒ Suppose that there are three stations labelled STA, STB, And STC, are transmitting while STB is receiving. The stations are in a configuration such that the two transmitters STA And STC are not in the radio range of each other. This is shown!

The above diagram shows that station STA starts transmitting to station STB. Since station STC. The frames received by STC are garbled and collision occurs. The situation is known as the hidden terminal problem.

solution: The Exposed terminal problem is solved by MAC (Medium Access Control)

Layer 2 protocol IEEE 802.11 RTS/CTS, with the condition that the stations are synchronized. And frame size and data speed are the same. RTS stands for Request to send and CTS stands for clear to send.

A transmitting station sends a RTS frame to the receiving station.

The receiving station replies by sending a CTS frame. On receipt of CTS frame, the transmitting station begins transmission.

Any station hearing the RTS is close to the transmitting station

and remains silent long enough for the CTS. Any station

hearing the ~~the~~ CTS is close to the receiving station and

remains transmission. In the above example, station STA

hears RTS from station STA, but hears CTS frame

from station STB. So it understands that STB is busy

Deterring its transmission thus avoiding collision.

⑤ (b) Answer: cell cluster: cells in a cellular Network  
are generally "grouped" together into cell clusters.  
Cellular Networks are generally designed as repeated  
cluster pattern. The Number of cells in a cluster  
(typically 4, 7, 12 or 21) is a trade-off between the  
traffic capacity in the cluster and its capacity in the  
cluster and its interference with the adjacent  
cluster of cells (where the same frequencies will be  
re-used)

Fig: cluster.

Answer to the Question - No - 1

Ans:

Traffic intensity per m =  $7 \cdot 48 = 1 \times (1160) \times 1 \cdot 5 = 0 \cdot 025 \text{ End/m}^2$

For each cell,  $n = 15$ ,  $B = 5\%$ .

$$A = 10 \cdot 633 \text{ End.}$$

$$\text{Number of users} = 500 + 425 \cdot 3.2 = \frac{212660}{212600}$$

$$\text{penetration rate} = (\text{Number of users} / \text{total population}) \times 100 \\ = (212660 / (3 \times 10^6)) \times 100 \\ = 7.09\%.$$

$$A_1 = 3, \text{ and } A_2 = 4$$

	3	4.5	18					
	2	4.5	9					
	1	3	6	6				
3	0	1	2	2	11.33			
2	choose 0	1	2	2	3			
$n_1 n_2$	1	2	2	2	11.33			

$$A_1 3 / 3! = 27 / 6 = 4.5$$

$$A_1 2 / 2! = 9 / 2 = 4.5$$

$$A_2 4 / 2! = 24 / 2 = 12$$

$$A_1 A_2 2 / 2! = 3 \times 2 / 2 = 6$$

$$A_2 2 / 2! = 4 \times 2 = 8$$

$$A_2 3 / 3! = 8 / 6 = 1.33$$

The sum of entire sampling,  $S = 198.264$ .
